# YET ANOTHER WAY TO IDENTIFY THE NORMAL DISTRIBUTION 

ERIC S. KEY

## 1. Introduction

We look at some new ways to identify normally distributed random variables. One of these is related to some problems in abnormal returns in stock prices.

## 2. Main Results

We begin with the following lemma.

Lemma 2.1. Suppose that $\phi$ is a characteristic function with $\phi^{\prime}(0)=0, \phi^{\prime \prime}(0)=$ $-\sigma^{2}<0$ and in some open neighborhood of 0 ,

$$
\begin{equation*}
a \phi^{\prime}(t) \phi(a t)=\phi^{\prime}(a t) \phi(t) \tag{2.1}
\end{equation*}
$$

for some $a$, where $a \neq 0, \pm 1$. Then $\phi(t)=\exp \left(-\sigma^{2} t^{2} / 2\right)$ for all real numbers $t$.

Proof. Without loss of generality we may assume that (2.1) holds for some $a$ with $0<|a|<1$. It follows from (2.1) that for all $t$ in some open neighborhood of 0 , and for all positive integers $n$

$$
\begin{equation*}
\frac{\phi^{\prime}(t)}{\phi(t)}=\frac{\phi^{\prime}\left(a^{n} t\right)}{a^{n} \phi\left(a^{n} t\right)} \tag{2.2}
\end{equation*}
$$

For such $t$ which are different from 0 , divide both sides of (2.2) by $t$ and let $n \rightarrow \infty$ to obtain

$$
\frac{\phi^{\prime}(t)}{t \phi(t)}=-\sigma^{2} .
$$

Therefore in an open neighborhood of 0 we have

$$
\phi^{\prime}(t)+\sigma^{2} t \phi(t)=0 .
$$

Therefore in an open neighborhood of 0 we have $\phi(t)=\exp \left(-\sigma^{2} t^{2} / 2\right)$. This implies that $\phi(t)=\exp \left(-\sigma^{2} t^{2} / 2\right)$ for all real numbers $t$ since the moments of the normal distribution uniquely characterize that distribution.

Theorem 2.2. Suppose that $X$ and $Y$ are independent random variables with standard deviations $\sigma_{X}>0$ and $\sigma_{Y}>0$ respectively, and $(X-\mathrm{E}[\mathrm{X}]) / \sigma_{\mathrm{X}}$ and $(Y-$ $\mathrm{E}[\mathrm{Y}]) / \sigma_{\mathrm{Y}}$ are identically distributed. Then there exists a constant $C$ such that

$$
\begin{equation*}
\mathrm{E}\left[(\mathrm{CX}-(1-\mathrm{C}) \mathrm{Y}) \mathrm{I}_{\mathrm{X}+\mathrm{Y} \leq \mathrm{t}}\right]=0 \tag{2.3}
\end{equation*}
$$

for all $t$ iff $C=\sigma_{Y}^{2} /\left(\sigma_{X}^{2}+\sigma_{Y}^{2}\right), C \mathrm{E}[\mathrm{X}]=(1-\mathrm{C}) \mathrm{E}[\mathrm{Y}]$, and either $X$ and $Y$ are identically distributed or $X$ and $Y$ are normally distributed.

Proof. We consider the easy direction first. Suppose that $C=\sigma_{Y}^{2} /\left(\sigma_{X}^{2}+\sigma_{Y}^{2}\right)$ and $C \mathrm{E}[\mathrm{X}]=(1-\mathrm{C}) \mathrm{E}[\mathrm{Y}]$. If $X$ and $Y$ are identically distributed then (2.3) is trivially true. If $X$ and $Y$ are normally distributed, then $C(X-\mathrm{E}[\mathrm{X}])-(1-\mathrm{C})(\mathrm{Y}-\mathrm{E}[\mathrm{Y}])$ and $X+Y$ are uncorrelated, and, therefore, independent. Therefore

$$
\mathrm{E}\left[(\mathrm{CX}-(1-\mathrm{C}) \mathrm{Y}) \mathrm{I}_{\mathrm{X}+\mathrm{Y} \leq \mathrm{t}}\right]=(\mathrm{CE}[\mathrm{X}]-(1-\mathrm{C}) \mathrm{E}[\mathrm{Y}]) \cdot \operatorname{Pr}(\mathrm{X}+\mathrm{aY} \leq \mathrm{t})=0
$$

as required.
Now for the interesting direction. Suppose that (2.3) holds. Letting $t \rightarrow \infty$ we see that $C \mathrm{E}[\mathrm{X}]-(1-\mathrm{C}) \mathrm{E}[\mathrm{Y}]=0$, so we have

$$
\begin{equation*}
\mathrm{E}\left[\left(\mathrm{C}(\mathrm{X}-\mathrm{E}[\mathrm{X}])-(1-\mathrm{C})(\mathrm{Y}-\mathrm{E}[\mathrm{Y}]) \mathrm{I}_{\mathrm{X}+\mathrm{Y} \leq \mathrm{t}}\right]=0\right. \tag{2.4}
\end{equation*}
$$

It follows from (2.4) that for all bounded continuous functions $f$,

$$
\begin{equation*}
\mathrm{E}[(\mathrm{C}(\mathrm{X}-\mathrm{E}[\mathrm{X}])-(1-\mathrm{C})(\mathrm{Y}-\mathrm{E}[\mathrm{Y}]) \mathrm{f}(\mathrm{X}+\mathrm{Y})]=0 \tag{2.5}
\end{equation*}
$$

If we take $f(u)=\exp (i t(u-\mathrm{E}[\mathrm{X}]-\mathrm{E}[\mathrm{Y}]))$ for any real number $t$, and let $\phi_{X}$ denote the characteristic function of $X-\mathrm{E}[\mathrm{X}]$ and let $\phi_{Y}$ denote the characteristic function of $Y-\mathrm{E}[\mathrm{Y}]$ it follows from (2.4) that

$$
\begin{equation*}
C \phi_{X}^{\prime}(t) \phi_{Y}(t)=(1-C) \phi_{Y}^{\prime}(t) \phi_{X}(t) \tag{2.6}
\end{equation*}
$$

since $X$ and $Y$ have finite mean. Dividing both sides of (2.6) by $t$ and letting $t \rightarrow 0$ gives $C \sigma_{X}^{2}=(1-C) \sigma_{Y}^{2}$ as required. If $\sigma_{X}=\sigma_{Y}$ then $X$ and $Y$ have the same mean and variance, so they are identically distributed. Suppose that $\sigma_{X} \neq \sigma_{Y}$. Let $\phi$ denote the common characteristic function of $(X-\mathrm{E}[\mathrm{X}]) / \sigma_{\mathrm{X}}$ and $(Y-\mathrm{E}[\mathrm{Y}]) / \sigma_{\mathrm{Y}}$. Then from (2.6) we have

$$
\begin{equation*}
\sigma_{Y}^{2} \sigma_{X} \phi^{\prime}\left(\sigma_{X} t\right) \phi\left(\sigma_{Y} t\right)=\sigma_{X}^{2} \sigma_{Y} \phi^{\prime}\left(\sigma_{Y} t\right) \phi\left(\sigma_{X} t\right) \tag{2.7}
\end{equation*}
$$

If we set $u=\sigma_{X} t$ and $a=\sigma_{Y} / \sigma_{X}$ in (2.7) we get

$$
a \phi^{\prime}(u) \phi(a u)=\phi^{\prime}(a u) \phi(u)
$$

and normality follows from the Lemma.

As an application of this theorem, we consider the following model for the return on a stock, $R$, given in Vachadze[2001]. $A, B$, and $J$ are independent random variables. $A$ and $B$ are normal, and $\operatorname{Pr}(J=1)=1-\operatorname{Pr}(J=0)=p \in(0,1)$, and it was assumed that $R=A+J B$. The idea is that under usual circumstances $R$ is distributed like $A$, but from time to time there is unusual information which changes the return distribution to be that of $A+B$.

It was subsequently shown in Vachadze[2002] that if we let $f_{X}$ denote the density of a random variable $X$ then

$$
\begin{equation*}
\mathrm{E}[\mathrm{~J} \mid \mathrm{R}]=\mathrm{p} \frac{\mathrm{f}_{\mathrm{A}+\mathrm{B}}(\mathrm{R})}{\mathrm{f}_{\mathrm{R}}(\mathrm{R})} \tag{2.8}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{E}[\mathrm{~J}(\mathrm{~B}-\mathrm{E}[\mathrm{~B}]) \mid \mathrm{R}]=\frac{\operatorname{Var}[\mathrm{B}]}{\operatorname{Var}[\mathrm{A}+\mathrm{B}]}(\mathrm{R}-\mathrm{E}[\mathrm{~A}+\mathrm{B}]) \mathrm{E}[\mathrm{~J} \mid \mathrm{R}] \tag{2.9}
\end{equation*}
$$

It is easy to check that (2.8) remains true so long as $A$ and $B$ have densities. The same is not true for (2.9). In fact, we have

Theorem 2.3. Suppose that $A, B$ and $J$ are independent random variables, that $A$ and $B$ have (absolutely) continuous distributions with variances $\sigma_{A}^{2}$ and $\sigma_{B}^{2}$ respectively, that $(A-\mathrm{E}[\mathrm{A}]) / \sigma_{\mathrm{A}}$ and $(B-\mathrm{E}[\mathrm{B}]) / \sigma_{\mathrm{B}}$ are identically distributed, and that $\operatorname{Pr}(J=1)=1-\operatorname{Pr}(J=0)=p \in(0,1)$. Put $R=A+J B$. If

$$
\begin{equation*}
\mathrm{E}[\mathrm{~J}(\mathrm{~B}-\mathrm{E}[\mathrm{~B}]) \mid \mathrm{R}]=\mathrm{C}(\mathrm{R}-\mathrm{D}) \mathrm{p} \frac{\mathrm{f}_{\mathrm{A}+\mathrm{B}}(\mathrm{R})}{\mathrm{f}_{\mathrm{R}}(\mathrm{R})} \tag{2.10}
\end{equation*}
$$

for some constants $C$ and $D$ then $C=\sigma_{B}^{2} /\left(\sigma_{A}^{2}+\sigma_{B}^{2}\right), D=\mathrm{E}[\mathrm{A}+\mathrm{B}]$, and if $\sigma_{A}^{2} \neq \sigma_{B}^{2}$ then $A$ and $B$ are normally distributed.

Proof. It follows from the definition of conditional expectation that if $F$ is any Borel subset of the real line then

$$
\begin{aligned}
p \mathrm{E}\left[(\mathrm{~B}-\mathrm{E}[\mathrm{~B}]) \mathrm{I}_{\mathrm{A}+\mathrm{B} \in \mathrm{~F}}\right] & =\mathrm{E}\left[(\mathrm{~B}-\mathrm{E}[\mathrm{~B}]) \mathrm{I}_{\mathrm{A}+\mathrm{B} \in \mathrm{~F}} \mathrm{I}_{\mathrm{J}=1}\right] \\
& =\mathrm{E}\left[\mathrm{~J}(\mathrm{~B}-\mathrm{E}[\mathrm{~B}]) \mathrm{I}_{\mathrm{A}+\mathrm{JB} \in \mathrm{~F}} \mathrm{I}_{\mathrm{J}=1}\right] \\
& =\mathrm{E}\left[\mathrm{~J}(\mathrm{~B}-\mathrm{E}[\mathrm{~B}]) \mathrm{I}_{\mathrm{R} \in \mathrm{~F}}\right] \\
& =p C \mathrm{E}\left[(\mathrm{R}-\mathrm{D}) \frac{\mathrm{f}_{\mathrm{A}+\mathrm{B}}(\mathrm{R})}{\mathrm{f}_{\mathrm{R}}(\mathrm{R})} \mathrm{I}_{\mathrm{R} \in \mathrm{~F}}\right] \\
& \left.=p C \int_{\mathbf{R}}(R-D) f_{A+B}(R) I_{F}(R) d R\right] \\
& =p C \mathrm{E}\left[(\mathrm{~A}+\mathrm{B}-\mathrm{D}) \mathrm{I}_{\mathrm{A}+\mathrm{B} \in \mathrm{~F}}\right]
\end{aligned}
$$

So

$$
\begin{equation*}
\mathrm{E}\left[(\mathrm{C}(\mathrm{~A}+\mathrm{E}[\mathrm{~B}]-\mathrm{D})-(1-\mathrm{C})(\mathrm{B}-\mathrm{E}[\mathrm{~B}])) \mathrm{I}_{\mathrm{A}+\mathrm{B} \in \mathrm{~F}}\right]=0 \tag{2.11}
\end{equation*}
$$

for each Borel subset of the real line. Taking $F=(-\infty, t+D]$ we see that Theorem 2.3 follows from Theorem 2.2.
